

What is a Tool?

The Hands of an AI Agent

An LLM Can Think – But It's Cut Off

Reasoning and language are native. But your database, your APIs, your order system? **Completely out of reach.**

The Doctor Analogy

A doctor can diagnose — but needs **instruments** to examine you. An LLM can reason — but needs **tools** to act.

The Core Mental Model

LLM = The Brain

Thinks, reasons, and decides what to do

Tools = The Hands

Execute actions in the real world on the brain's behalf

A Tool is Just a Python Function

```
def get_order_details(order_id):  
    order = Order.objects.get(id=order_id)  
    return {  
        "status": order.status,  
        "carrier": order.carrier,  
        "tracking": order.tracking_number,  
    }
```

Your Django ORM

Wrapped so an AI agent can call it directly.

- ❗ No new paradigm — just a function with a description.

Who Decides When It Runs?

Traditional Django

URL → View → Function

You wire up the route. You control when it fires.

Agentic AI

AI Agent → decides → Function runs

The agent chooses — based on what the user asked.

The Agent Reads, Then Decides

The description is the agent's guide. It calls the tool only when it helps.

Tool = Function + Schema

```
{
  "name": "get_order_details",
  "description": "Fetch order details including
    status, carrier, and tracking number.",
  "input_schema": {
    "type": "object",
    "properties": {
      "order_id": {
        "type": "integer",
        "description": "The order ID to look up"
      }
    },
    "required": ["order_id"]
  }
}
```

What the LLM Actually Reads

The schema tells the model **when** to call your function and **how** to call it.

- ❏ The description is the most important field — it drives the decision.
